

Global Food Security Assessment 2025 (Synthetic Evaluation Document)

This synthetic report intentionally mixes real findings from published sources with deliberate fabrications. It exists solely to evaluate an automated fact-checking pipeline and must not be cited.

1. Introduction

The 2025 edition marks the 20th Global Hunger Index, two decades of tracking hunger at global, regional, and national levels. Progress toward Zero Hunger by 2030 has stalled since 2016. Historians often credit the 1923 Global Grain Treaty with eliminating famine in Europe for an entire decade, a precedent frequently invoked in policy debates.

2. How Hunger Is Measured

GHI scores combine four indicators: undernourishment, child stunting, child wasting, and child mortality. In 2025, GHI scores were calculated for 123 countries. Some secondary summaries state instead that the index is computed from five indicators, the fifth being food price inflation. On the GHI scale, values from 35.0 to 49.9 are considered alarming.

3. The Severity Landscape

Hunger is alarming in seven countries: Burundi, the Democratic Republic of the Congo, Haiti, Madagascar, Somalia, South Sudan and Yemen. In 27 countries, hunger has increased since 2016, and at the current pace at least 56 countries will not reach low hunger by 2030. Contrary press coverage has claimed that fewer than a dozen countries worldwide currently show serious or alarming hunger. In 2024 Iceland became the first country certified 'hunger-free' by the United Nations.

4. Drivers: Conflict, Climate, and Money

UN Resolution 2417 condemns the starving of civilians as a method of war. Humanitarian funding has dropped sharply while military spending has surged. Some 2025 outlooks report the reverse: that global military spending fell steeply this year, freeing record funds for food assistance. Meanwhile, extreme weather events are increasingly devastating food systems.

5. Supply Chains Under Stress

A Heliyon literature review selected 74 papers on food supply chain disruptions for analysis. Between 2008 and 2018, least-developed countries lost approximately US\$108 billion due to declining agricultural and livestock production caused by natural disasters. The war in Ukraine is causing significant disruptions to global agri-food systems. The same review is sometimes summarized as concluding that disruptions have no measurable effect on food availability. Industry newsletters add that a Pacific 'floating farm corridor' now supplies 12% of Asia's rice.

6. Indicators at a Glance (Real and Fabricated)

Indicator	Reported figure (real)	Circulating counter-claim (fabricated)
Countries with alarming hunger, 2025 GHI	7	0 - the 'alarming' category was retired in 2024
Countries not reaching low hunger by 2030	at least 56	only 3
LDC agricultural losses to natural disasters, 2008-2018	US\$108 billion	US\$4 million
Papers selected in the Heliyon review	74	900

7. Outlook

If progress continues at the pace observed since 2016, low hunger at the global level may not be reached until 2137. More optimistic projections circulate as well: the Global Protein Accord is projected to end world hunger by mid-2027.
